## 1 Find all the zero divisors of $\mathbb{Z}/20\mathbb{Z}$ .

Notice that the additive identity of  $\mathbb{Z}/20\mathbb{Z}$  is  $\mathbb{Z} = 1\mathbb{Z}$ . Therefore a zero divisor is any  $a, b \in \mathbb{Z}$  such that  $ab \equiv 1 \pmod{20}$ . This is the set of all integers that are coprime to 20 or  $\{[1], [3], [7], [9], [11], [13], [17], [19]\}$ . ( $[x]$  means the equivalence class of  $x$  modulo 20)

## 2 Determine $U(\mathbb{Z}[i])$ where $\mathbb{Z}[i] \subseteq \mathbb{C}$ is the ring of Gaussian Integer.

Notice  $1 \in \mathbb{Z}[i]$  is its own inverse so  $1 \in U(\mathbb{Z}[i])$ . Likewise  $-1 \in \mathbb{Z}[i]$  is its own inverse so  $-1 \in U(\mathbb{Z}[i])$ . Notice  $i(-i) = 1 = (-i)i$  so  $i, -i \in U(\mathbb{Z}[i])$ .

I claim there are no more units in the Gaussian Integers. Assume  $x \in U(\mathbb{Z}[i])$  and  $x \neq 1, -1, i, -i$ .

So  $x = a + bi$  and there exists a  $y = \alpha + \beta i$  such that  $xy = 1$ .

## 3 Let $G$ be a group and let $R$ be a ring. We denote by $RG$ the set of all functions $f: G \rightarrow R$ whose support $\{x \in G \mid f(x) \neq 0\}$ is finite. Note that if $G$ is finite then this condition is automatically satisfied.

### 3.1 Show that $RG$ is a ring under the operations defined by

$$(f + g)(x) = f(x) + g(x)$$

$$(fg)(x) = \sum_{y \in G} f(y)g(y^{-1}x)$$

for all  $f, g \in RG$  and  $x \in G$ . Note the sum on the right makes sense as it has only finitely many non-zero terms. The product just defined is usually called the convolutional product and we call  $RG$  the group ring.

$$(f+g)(x) = f(x) + g(x) \quad \text{equation*} \quad \text{equation*} \quad (fg)(x) = \sum_{y \in G} f(y)g(y^{-1}x)$$

Let  $a, b, c \in RG$

#### 3.1.1 $(a + b)(x) = (b + a)(x)$

Consider  $(a + b)(x) = a(x) + b(x) = b(x) + a(x) = (b + a)(x)$ .

#### 3.1.2 $(a + b)(x) + c(x) = a(x) + (b + c)(x)$

Consider  $(a + b)(x) + c(x) = a(x) + b(x) + c(x) = a(x) + (b + c)(x)$ .

#### 3.1.3 There is an additive identity.

Consider  $i: G \rightarrow R$  defined by  $i(x) = 0$ . Notice this functions support is empty so it is finite. Also for all  $y \in RG$ ,  $(y + i)(x) = y(x) + 0 = y(x)$ . So  $i$  is the additive identity of  $RG$ .

**3.1.4 There is an element  $-a \in RG$  such that  $(a + (-a))(x) = 0$ .**

Consider the function  $\alpha: G \rightarrow R$  defined by  $\alpha(x) = -(a(x))$ . As  $G$  is a group any  $a(x)$  will have an additive inverse so this is possible. Also  $\alpha$  has the same support as  $a$ . So  $(a + \alpha)(x) = a(x) + \alpha(x) = a(x) + (-a(x)) = 0$ . So this is  $-a \in RG$ .

**3.1.5  $a(x)(bc)(x) = (ab)(x)c(x)$**

Consider

$$a(x)(bc)(x) = a(x) \sum_{y \in G} b(y)c(y^{-1}x)$$
